### 1.1 Objective

The aim of this document is calculation of MTBF & MTTR (Reliability) of EICS to be applied to Water Transmission Pipe line From Kousar Dam To Gachsaran Ptrochemical Co. Project. Reliability refers to the capability of this system and technical equipment to fulfill its function during its operating period. This is usually no longer the case if any of its components fails. So a commonly used measure for reliability is the MTBF (Mean Time between Failures). This can be analyzed statistically based on the parameters of running systems, or by calculating the failure rates of the components used.

### 1.2 Document management

This document is created by Control Sazan Company engineering department and it is a description of control system to achieve more recognition of system.

### 1.3 Abbreviations

CS:	Control System
MTTR:	Mean Time to Repair
MTBF:	Mean Time between Failures
MDT:	Mean Down Time
OSM:	Optical Switch Module
ESM:	Electrical Switch Module
CPU:	Central Processing Unit
PLC:	Programmable Logic Controller

## 2. MTTR Calculation

The use of redundant modules considerably prolongs the MTBF of a system. The combination of integrated high-quality self-tests and error detection mechanisms of the S7-400H CPUs allow the detection and localization of virtually all errors. The MTBF of an S7-400H is determined by the MDT (Mean down Time) of a system unit. This time is derived in essence from the error detection time plus the time required repairing or replacing defective modules. In addition to other measures, a CPU provides a self-test function with an adjustable test cycle time. The default test cycle time is 90 minutes. This time has an influence on the error detection time. The repair time usually required for a modular system such as the S7-400H is four hours.

## 3. MTBF Calculation

### 3.1 Modeling of the system

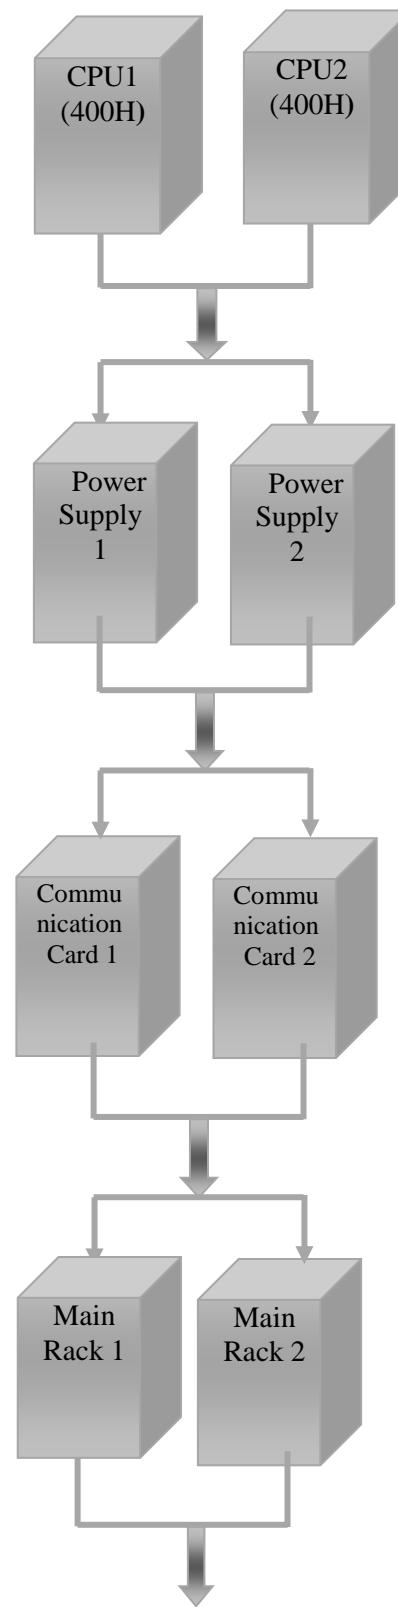

The elements that affect the availability factor in this system are as follow:

- CPUs
- Main rack power supplies
- Power supplies for I/O cards
- Communication cards

So based on the above elements the system will be modeled as follows:

Model for PDCS:

نگهداشت و افزایش تولید میدان نفتی بینک

سطح الارض

**Control Sazan**  
Pooyande Co.

### 3.2 PDCS MTBF Calculation

The value of MTBF for each equipment have been read from the attachment table which is obtained from SIEMENS website ([automation.siemens.com](http://automation.siemens.com))

MTBF for individual main PLC equipment:

Modules	MTBF (Years)
CPU	23
CP443-1	40.6
POWER SUPPLY 407	60
ETHERNET SWITCH	132.9
IM 153-2	106
CP	145.6
DI	30.6
DO	16.5
AI	61
RACK	291

#### Modules MTBF (Years)

MTBF for redundant system of PDCS:

$$MTBF_{TOTAL} = MTBF_{MASTER} \times MTBF_{RESERVE}$$

$$(MTBF_{MASTER})^{-1} = (MTBF_{CPU})^{-1} + (MTBF_{PS})^{-1} + (MTBF_{CP})^{-1} + (MTBF_{ES})^{-1}$$

$$(MTBF_{RESERVE})^{-1} = (MTBF_{MASTER})^{-1} = (23)^{-1} + (60)^{-1} + (40.6)^{-1} + (132.9)^{-1}$$

$$\rightarrow MTBF_{MASTER} = MTBF_{RESERVE} = 12.49 \text{ Years.}$$

$$\rightarrow MTBF_{TOTAL} = 156 \text{ Years.}$$

## Mean Time Between Failures (MTBF)

service  
& SUPPORT

Background information on MTBF

**SIEMENS**

## What is this about?

The Mean Time Between Failures (MTBF) is a statistical mean value for error-free operation of an electronic device. The specification of this statistical value in years often leads to it being wrongly interpreted as the service life of the component. Therefore, below we will show you

- What is to be understood by service life and MTBF.
- How to use the MTBF to determine the probability of failure.

## What is to be understood by service life?

The service life is the time for which the device or component is designed to function. This, therefore, is the time up to the beginning of the wear-and-tear phase through a physical law or aging due to chemical reactions. In the case of devices with electromechanical parts (relays), the service life is mainly defined by the number of operations and the load connected.

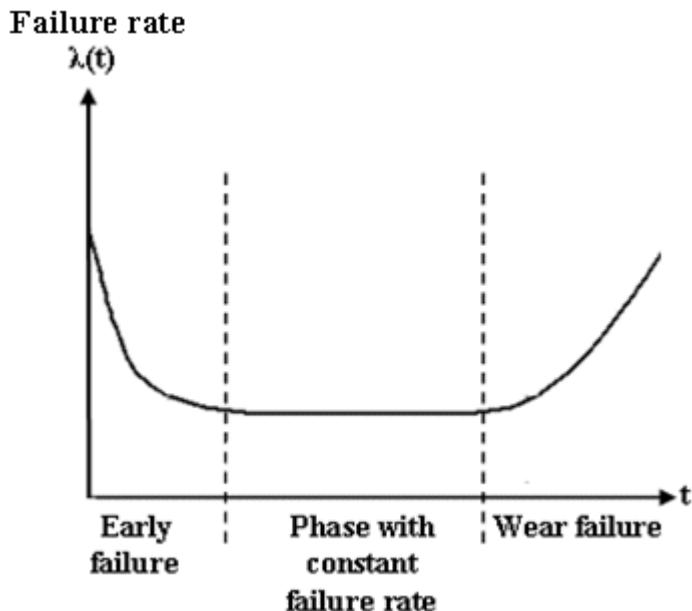

## What is to be understood by MTBF?

The MTBF does not apply to an individual component, but is a statistical mean value for the average time between two failures during the normal working life. The MTBF always refers to the phase with constant failure rate (i.e. without early or wear failures (see "bathtub curve" figure)).

The higher the MTBF, the less often the component concerned fails and the more reliable it is. According to DIN 40041, reliability is understood to be the "the property of an entity to fulfill its reliability requirements during or after a given time span under given application conditions". You must note here that in addition to the MTBF value, the environment and operating conditions (in particular temperature), the failure criteria and the duration of the value's validity must be specified and taken into consideration. If a device is operated under conditions beyond its specification (e.g. at extremely high ambient temperatures or subject to a massive EMC load), then the MTBF values are no longer valid and large numbers of failures might occur.

## Bathtub curve

The reciprocal value of the MTBF that is a measure for the reliability of a component is the failure rate  $\lambda$ . Plotting of the statistical failure rate  $\lambda$  over time  $t$  gives the bathtub function shown below (bathtub curve).

## Failure rate

Failure rates have the dimension of 1/time unit. The term FIT (failures in time) is also often used for individual components. This describes a failure rate with reference to a relevant time base:  $1 \text{ FIT} = 10^{-9} \text{ h}^{-1}$ .

The MTBF is determined by adding together the FIT values of the individual components.

The early failure phase is mainly characterized by defective components that are identified during manufacture and in the end are not available to the user. The wear failure phase is defined mainly by the wear and tear of the components. The phase with the constant failure rate is the useful life of the component. During this time you can assume a defined (constant) failure of the components.

## Probability of failure

An exponential distribution is used to define the probability of failure of electronic and electromechanical components. The following holds:

$$F(t) = 1 - e^{-\lambda t}$$

Where

- $F(t)$  is the probability of failure
- $\lambda$  is the failure rate in 1/time unit (1/h, for example)
- $t$  is the observed service life (h, for example)

This correlation applies only for the phase of constant failure rate in the bathtub curve, i.e. for  $\lambda = \text{constant}$ . Under these conditions, the relationship below holds for the MTBF:

$$\text{MTBF} = 1 / \lambda \text{ or } \lambda = 1 / \text{MTBF}$$

If you now replace the failure rate  $\lambda$  in  $F(t)$ , you get the following result:

$$F(t) = 1 - e^{(-t/\text{MTBF})}$$

Thus, you can easily calculate the probability of failure from the MTBF specified by the manufacturer and an assumed constant failure rate.

## Example

After one year's delivery, there are 20,000 components in the field with an MTBF of 60 years. How high is the probability of failure of the components?

With  $F(t) = 1 - e^{(-t/\text{MTBF})}$  where  $t=1$  and  $\text{MTBF}=60$  the result is:

$F(t) = 0.0165$ , which means that the probability of failure of the components is 1.65%. For the assumed 20,000 components this means that from the statistical point of view 330 components may fail within one year. However, practice has shown that with electronic components in particular, there are much less failures.

**Determining the MTTF<sub>D</sub> from the MTBF**

The MTTF (**M**ean **T**ime **t**o failure) and MTTF<sub>D</sub> (**M**ean **T**ime **t**o failure **d**angerous) are the mean time to failure and mean time to dangerous failure respectively. In practice you can determine the MTTF or MTTF<sub>D</sub> with known MTBF using the relationships below.

$$\text{MTTF} = 1 / \lambda \text{ or } \lambda = 1 / \text{MTTF} \text{ (basic equation from IEC 62061)}$$

In this way, the MTBF values are equivalent to the MTTF values also in the context of ISO 13849-1. However, this only applies for as long as there are no dangerous failures (MTTF without index "d").

When considering dangerous failures, it is assumed that statistically only every other failure is a potentially dangerous failure. The following thus holds:

$$\text{MTTF}_D = 2 \cdot \text{MTTF}$$

With equalization of MTTF and MTBF the result is:

$$\text{MTTF}_D = 2 \cdot \text{MTBF}$$

This relationship that complies with IEC 61508 and ISO 13849-1 holds for electronic components under the following conditions:

- The permissible ambient conditions must be met.
- The Mean Time to Repair (MTTR) is significantly less than the MTBF.

# Reliability Consulting

## Reliability / Availability

### Description:

Nowadays, many terms which are part of the *Reliability Engineering* jargon are derived from the daily life's vocabulary. Even though these terms are, generally speaking, "comprehensible", they require to be delimitated and defined within the proper context, in order to have a clear understanding of what is *Reliability Engineering* about.

According to IEEE... /IEC... /MIL... /DIN..., **Reliability** can be defined as "the ability of an item to perform a required function specified by its intended purpose, under stated conditions during a given period of time".

Notwithstanding Reliability is not a quantifiable magnitude, all quantitative observations, as the quality of a system, refer to a finite and delimitated period of observations, in other words, the duration of the mission.

Moreover, in Reliability Engineering, Availability (A) is used as a quantitative magnitude.

According to IEEE... /IEC... /MIL... /DIN..., **Availability** refers to the probability of finding an item in an operational state at a given time". Accordingly, availability is the relationship between two times, namely the average time of failure-free operation (during the mission) and the overall duration of the mission.

Furthermore, the average time of failure-free operation during the mission is known as the **Mean Time Between Failure (MTBF)**. This term is based on the assumption that when a failure occurs, the system does not generally remain in the down state for the rest of time the mission lasts, but is renewed or repaired.

Additionally, the time required for renewal or repair (i.e. from the start of the down state to the restoration of the up state) is known as the **Mean Time to Repair (MTTR)**, often also called **Mean Down Time (MDT)**.

If repairs are always carried out upon occurrence of a failure, then the duration of the mission is the sum of MTBF and MTTR. For this standard, a practical case of availability is:

$$A = \text{MTBF} / (\text{MTBF} + \text{MTTR})$$

Since technical systems are generally accepted and implemented only when they have high availability, A is a figure that is less (but very close) than 1.

# Reliability Consulting

**MTBF = Mean Time Between Failure** (average failure-free time)

The term MTBF applies to parts, components, modules, subsystems, systems and plants.  
In most cases the stress factor temperature of 40 degrees (C) is taken as a basis.

**Calculations** for parts, components and modules are based on the following standards

IEC 61709, SN 29500 and MIL-HDBK-217F

The "Parts Count" standard applies in this case. For instance, all component's failure rates are considered, regardless of the associated structure added (this does not apply to non-redundant system structures).

$$1 / (\text{MTBF}_{\text{total}}) = 1 / (\text{MTBF}_{\text{part 1}}) + \dots + 1 / (\text{MTBF}_{\text{part n}})$$

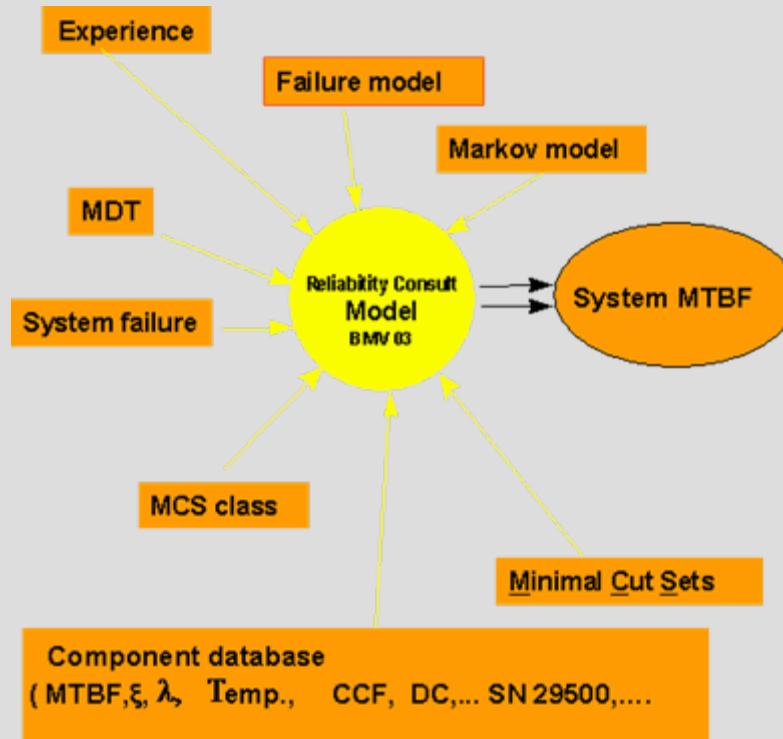

# Reliability Consulting

Calculations for subsystems, systems and plants are based on the following standards:

IEEE 352, IEC 60300-3-1,  
IEC 61069-5, MIL-STD 756B,  
MIL-HDBK 338B.....

A model is constructed  
based on the components,  
taking into account  
the associated structure.

$$MTBF_{total} = f(MTBF_{comp}, MTTR, CCF, DC, temp., \xi, structure, \dots)$$
